

A Newt's Life

A newt is an amphibian. Amphibians start their lives in water. As adults they live on land.

A female newt lays her eggs in a pond.
A newt larva forms inside each egg.

A tiny larva hatches from an egg.
At two months old it grows front legs.

The larva gets bigger and its back legs grow.

Young amphibians breathe underwater through body parts called gills. Once they are adults, they breathe in air through their skin and with lungs.

When it is about five months old, a young newt is ready to live on land.
